

1. Assuming we have a function `get_inode(char* dir)` that returns inode number of the directory passed in `dir` string. If the condition of the following code is true then what you can say about the directory?
`if (get_inode("../") == get_inode("."))`
2. What will be the entries in the Process File Descriptor and System-Wide File Open Tables after the following code is executed?

```
char buf1[100];  
int fd1 = open("file1.txt", O_RDWR);  
read(fd1, buf1, 20);  
int fd2 = open("file1.txt", O_RDWR);  
write(fd2, buf1, 10);
```
3. Assuming that `file1.txt` has "123456789012345678901234567890", what will be the content of the file after the code from Q2 is executed?
4. What are the two ways to ensure that the executable file can be executed from any directory even if it does not exist?
5. Write a shell script to copy the file without using `cp` command.
6. Write a shell script to display the content of all text files with `txt` extension (`*.txt`) from the current directory.
7. Assume that FCB has 10 pointers (pointer size of 4 bytes) to the data block, with each data block having a 1kB size. Therefore, the maximum size of the file you can have is $10 \times 1\text{kB} = 10\text{kB}$. If you want to support the file size up to 1MB, How can you support this using indirect pointers?
